The cost (also called metric) of an interface in OSPF is an indication of the overhead required to send packets across a certain interface. The cost of an interface is inversely proportional to the bandwidth of that interface. A higher bandwidth indicates a lower cost. There is more overhead (higher cost) and time delays involved in crossing a 56k serial line than crossing a 10M Ethernet line. The formula used to calculate the cost is: Cost = 10000000/bandwidth in bps
For example, it will cost $10 \text{ EXP}8 / 10 \text{ EXP}7 = 10$ to cross a 10M Ethernet line and will cost $10 \text{ EXP}8 / 1544000 = 64$ to cross a T1 line. By default, the cost of an interface is calculated based on the bandwidth; you can force the cost of an interface with the ip ospf cost <value> interface subconfiguration mode command.
