NEW QUESTION: 3 What is an advantage of sub-LUN tiering? **A. Improved performance B. Dynamic expansion of storage capacity C. Enhanced reliability and availability D. Faster provisioning of thin LUNs Answer: A** Explanation: Intra-array Storage Tiering The process of storage tiering within a storage array is called intra-array storage tiering. It enables the efficient use of SSD, FC, and SATA drives within an array and provides performance and cost optimization. The goal is to keep the SSDs busy by storing the most frequently accessed data on them, while moving out the less frequently accessed data to the SATA drives. Data movements executed between tiers can be performed at the LUN level or at the sub-LUN level. The performance can be further improved by implementing tiered cache. Traditionally, storage tiering is operated at the LUN level that moves an entire LUN from one tier of storage to another. This movement includes both active and inactive data in that LUN. This method does not give effective cost and performance benefits. Today, storage tiering can be implemented at the sub-LUN level. In sub-LUN level tiering, a LUN is broken down into smaller segments and tiered at that level. Movement of data with much finer granularity, for example 8 MB, greatly enhances the value proposition of automated storage tiering. Tiering at the sub-LUN level effectively moves active data to faster drives and less active data to slower drives. EMC E10-001 Student Resource Guide. Module 15: Managing the Storage Infrastructure

NEW QUESTION: 4 There is a 14-day backpacking tour across Europe. The tour coordinators are using a Kinesis Stream and IOT sensors to monitor the movement of the group. You have changed the default settings on the stream to the max settings. Each backpack has a sensor

and data is getting back to the stream with the default stream settings. On the last day of the tour, data is sent to S3. When you go to interpret the data in S3 there is only data for 7 days. Which of the following is the most probable cause of this? Choose the correct answer: **A.** Data records are only accessible up to 7 days from the time they are added to a stream. **B.** You needed to use EMR to send the data to S3; Kinesis Streams are only compatible with DynamoDB. **C.** You did not have versioning enabled and would need to create individual buckets to prevent the data from being overwritten. **D.** One of the sensors failed, so there was no data to record. **Answer: A** Explanation: Streams supports changes to the data record retention period of your stream. An Amazon Kinesis stream is an ordered sequence of data records meant to be written to and read from in real-time. Data records are therefore stored in shards in your stream temporarily. The time period from when a record is added to when it is no longer accessible is called the retention period. An Amazon Kinesis stream stores records from 24 hours by default, up to 168 hours.
