**NEW QUESTION: 2**You manage an on-premises, multi-tier application that has the following configuration:Two SQL Server 2012 databases named SQL1 and SQL2Two application servers named AppServer1 and AppServer2 that run IISYou plan to move your application to Azure.You need to ensure that during an Azure update cycle or a hardware failure, the application remains available.Which two deployment configurations should you implement? Each correct answer presents part of the solution.A. Deploy all servers in a single availability set.B. Deploy SQL1 and AppServer1 in a single availability set.C. Deploy AppServer1 and AppServer2 in a single availability set.D. Deploy SQL1 and SQL2 in a single availability set.E. Deploy SQL2 and AppServer2 in a single availability set.**Answer: C,D**Explanation:You should deploy AppServer1 and AppServer2 in a single availability set.You should deploy SQL1 and SQL2 in a single availability set.Note: Using availability sets allows you to build in redundancy for your Azure services. By grouping related virtual machines and services (tiers) into an availability set (in this case, deploying both of your databases into an availability set), you ensure that if there is a planned or unplanned outage, your services will remain available. At the most basic level, virtual machines in an availability set are put into a different fault domain and update domain. An update domain allows virtual machines to have updates installed and then the virtual machines are rebooted together.If you have two virtual machines in an availability set, each in its own update domain, a rebooting of one server does not bring down all of the servers in a given tier. A fault domain operates in the same manner, so if there is a physical problem with a server, rack, network, or other service, both machines are separated, and services will continue.Incorrect Answers:B: You should not deploy all servers in a single availability set. This will not provide the fault tolerance needed, as all machines would be rebooted (or suffer a hardware failure) together.C: SQL1 and AppServer1 provide different services, so they should not be grouped together.D: You should not deploy SQL2 and AppServer2 in a single availability set. SQL2 and AppServer2 provide different services, so they should not be grouped together.

**NEW QUESTION: 3** View the Exhibit to examine the output produced by the following query at three different times since the database instance started and has experienced workloads of different capacities: SQL> SELECT substr(component, 0, 10) COMP, current\_size CS, user\_specified\_size US FROM v\$memory\_dynamic\_components WHERE current\_size != 0; What do you infer from this? Exhibit: **A.** The database instance is running with manual shared memory management. **B.** The database instance is running with manual PGA management. **C.** All sessions are connected to the database instance in dedicated mode, and no RMAN or parallel query operations have been performed. **D.** The database instance has the MEMORY\_TARGET value set to a nonzero value. **Answer: D** Explanation: MEMORY\_TARGET specifies the Oracle system-wide usable memory. The database tunes memory to the MEMORY\_TARGET value, reducing or enlarging the SGA and PGA as needed. In a text-based initialization parameter file, if you omit MEMORY\_MAX\_TARGET and include a value for MEMORY\_TARGET, then the database automatically sets MEMORY\_MAX\_TARGET to the value of MEMORY\_TARGET. If you omit the line for MEMORY\_TARGET and include a value for MEMORY\_MAX\_TARGET, the MEMORY\_TARGET parameter defaults to zero. After startup, you can then dynamically change MEMORY\_TARGET to a nonzero value, provided that it does not exceed the value of MEMORY\_MAX\_TARGET.

**NEW QUESTION: 4** Excitation, increased alertness, euphoria, increased pulse rate and blood pressure, insomnia, and loss of appetite are symptoms of: **A.** Benzodiazepines **B.** Hallucinogens **C.** Marijuana **D.** Depressants **E.** Stimulants **Answer: E**
