The cost (also called metric) of an interface in OSPF is an indication of the overhead required to send packets across a certain interface. The cost of an interface is inversely proportional to the bandwidth of that interface. A higher bandwidth indicates a lower cost. There is more overhead (higher cost) and time delays involved in crossing a 56k serial line than crossing a 10M Ethernet line. The formula used to calculate the cost is: $\text{Cost} = \frac{10000000}{\text{bandwidth in bps}}$ For example, it will cost $\frac{10^8}{10^7} = 10$ to cross a 10M Ethernet line and will cost $\frac{10^8}{1544000} = 64$ to cross a T1 line. By default, the cost of an interface is calculated based on the bandwidth; you can force the cost of an interface with the `ip ospf cost <value> interface` subconfiguration mode command.
