NEW QUESTION: 1Which scanning is one of the more unique scan types, as it does not exactly determine whether the port is open/closed, but whether the port is filtered/unfiltered?**A.** ACK scanning**B.** UDP scanning**C.** TCP SYN scanning**D.** TCP FIN scanning**Answer: A****Explanation:**ACK scanning is one of the more unique scan types. It determines whether the port is filtered or unfiltered instead of determining whether the port is open or closed. This is especially good when attempting to explore for the existence of a firewall and its rule-sets. In TCP SYN/ACK scanning, an attacker sends a SYN/ACK packet to the target port. If the port is closed, the victim assumes that this packet was mistakenly sent by the attacker, and sends the RST packet to the attacker. If the port is open, the SYN/ACK packet will be ignored and the port will drop the packet. TCP SYN/ACK scanning is stealth scanning, but some intrusion detection systems can detect TCP SYN/ACK scanning. Answer option B is incorrect. TCP SYN scanning is also known as half-open scanning because in this type of scanning, a full TCP connection is never opened. The steps of TCP SYN scanning are as follows:1. The attacker sends a SYN packet to the target port. 2.If the port is open, the attacker receives the SYN/ACK message.3.Now the attacker breaks the connection by sending an RST packet.4.If the RST packet is received, it indicates that the port is closed.This type of scanning is hard to trace because the attacker never establishes a full 3-way handshake connection and most sites do not create a log of incomplete TCP connections. Answer option A is incorrect. UDP scan is little difficult to run. UDP is a connectionless protocol so there is no equivalent to a TCP SYN packet. However, if a UDP packet is sent to a port that is not open, the system will respond with an ICMP port unreachable message. Most UDP port scanners use this scanning method, and use the absence of a response to infer that a port is open. However, if a port is blocked by a firewall, this method will falsely report that the port is open. If the port unreachable message is blocked, all ports will appear open. This method is also affected by ICMP rate limiting. Answer option C is incorrect. TCP FIN scanning is a type of stealth scanning through which the attacker sends a FIN packet to the target port. If the port is closed, the victim assumes that this packet was sent mistakenly by the attacker and sends the RST packet to the attacker. If the port is open, the FIN packet will be ignored and the port will drop that packet. TCP FIN scanning is useful only for identifying ports of non-Windows operating systems because Windows operating systems send only RST packets irrespective of whether the port is open or closed.
