NEW QUESTION: 3 You are developing an application that will convert data into multiple output formats. The application includes the following code. (Line numbers are included for reference only.) You are developing a code segment that will produce tab-delimited output. All output routines implement the following interface: You need to minimize the completion time of the GetOutput() method. Which code segment should you insert at line 06? **A.** Option A **B.** Option C **C.** Option D **D.** Option B **Answer: D** Explanation: Explanation/Reference: Explanation: A String object concatenation operation always creates a new object from the existing string and the new data. A StringBuilder object maintains a buffer to accommodate the concatenation of new data. New data is appended to the buffer if room is available; otherwise, a new, larger buffer is allocated, data from the original buffer is copied to the new buffer, and the new data is then appended to the new buffer. The performance of a concatenation operation for a String or StringBuilder object depends on the frequency of memory allocations. A String concatenation operation always allocates memory, whereas a StringBuilder concatenation operation allocates memory only if the StringBuilder object buffer is too small to accommodate the new data. Use the String class if you are concatenating a fixed number of String objects. In that case, the compiler may even combine individual concatenation operations into a single operation. Use a StringBuilder object if you are concatenating an arbitrary number of strings; for example, if you're using a loop to concatenate a random number of strings of user input.
