NEW QUESTION: 3Which of the following is true about link encryption?**A.** Only secure nodes are used in this type of transmission.**B.** Encrypted messages are only decrypted by the final node.**C.** This mode does not provide protection if anyone of the nodes along the transmission path is compromised.**D.** Each entity has a common key with the destination node.**Answer: C**
Explanation:In link encryption, each entity has keys in common with its two neighboring nodes

in the transmission chain. Thus, a node receives the encrypted message from its predecessor, decrypts it, and then re-encrypts it with a new key, common to the successor node. Obviously, this mode does not provide protection if anyone of the nodes along the transmission path is compromised. Encryption can be performed at different communication levels, each with different types of protection and implications. Two general modes of encryption implementation are link encryption and end-to-end encryption. Link encryption encrypts all the data along a specific communication path, as in a satellite link, T3 line, or telephone circuit. Not only is the user information encrypted, but the header, trailers, addresses, and routing data that are part of the packets are also encrypted. The only traffic not encrypted in this technology is the data link control messaging information, which includes instructions and parameters that the different link devices use to synchronize communication methods. Link encryption provides protection against packet sniffers and eavesdroppers. In end-to-end encryption, the headers, addresses, routing, and trailer information are not encrypted, enabling attackers to learn more about a captured packet and where it is headed.
