The cost (also called metric) of an interface in OSPF is an indication of the overhead required to send packets across a certain interface. The cost of an interface is inversely proportional to the bandwidth of that interface. A higher bandwidth indicates a lower cost. There is more overhead (higher cost) and time delays involved in crossing a 56k serial line than crossing a 10M Ethernet line. The formula used to calculate the cost is:  $\text{Cost} = 100000000 / \text{bandwidth in bps}$   
For example, it will cost  $100000000 / 10000000 = 10$  to cross a 10M Ethernet line and will cost  $100000000 / 1544000 = 64$  to cross a T1 line. By default, the cost of an interface is calculated based on the bandwidth; you can force the cost of an interface with the `ip ospf cost <value> interface` subconfiguration mode command.
