NEW QUESTION: 2 What term is used to describe a cryptographic technique for embedding information into something else for the sole purpose of hiding that information from the casual observer?**A.** Key escrow**B.** Steganography**C.** Offset**D.** Rootkit**Answer: B**

NEW QUESTION: 3 Your company has a branch office that is configured as a separate Active Directory site and has an Active Directory domain controller. The Active Directory site requires a local Global Catalog server to support a new application. You need to configure the domain controller as a Global Catalog server. Which tool should you use?**A.** The Dcpromo.exe utility**B.** The Active Directory Domains and Trusts console**C.** The Computer Management console**D.** The Server Manager console**E.** The Active Directory Sites and Services console**Answer: E**
Explanation: <http://technet.microsoft.com/en-us/library/cc781329%28v=ws.10%29.aspx>
Configure a domain controller as a global catalog server
To configure a domain controller as a global catalog server
1. Open Active Directory Sites and Services. ...Further information:
<http://technet.microsoft.com/en-us/library/cc728188%28v=ws.10%29.aspx>
What Is the Global Catalog?
The global catalog is a distributed data repository that contains a searchable, partial representation of every object in every domain in a multidomain Active Directory Domain Services (AD DS) forest. The global catalog is stored on domain controllers that have been designated as global catalog servers and is distributed through multimaster replication. Searches that are directed to the global catalog are faster because they do not involve referrals to different domain controllers. In addition to configuration and schema directory partition replicas, every domain controller in a forest stores a full, writable replica of a single domain directory partition. Therefore, a domain controller can locate only the objects in its domain. Locating an object in a different domain would require the user or application to provide the domain of the requested object. The global catalog provides the ability to locate objects from

any domain without having to know the domain name. A global catalog server is a domain controller that, in addition to its full, writable domain directory partition replica, also stores a partial, read-only replica of all other domain directory partitions in the forest. The additional domain directory partitions are partial because only a limited set of attributes is included for each object. By including only the attributes that are most used for searching, every object in every domain in even the largest forest can be represented in the database of a single global catalog server. Note: A global catalog server can also store a full, writable replica of an application directory partition, but objects in application directory partitions are not replicated to the global catalog as partial, read-only directory partitions. The global catalog is built and updated automatically by the AD DS replication system. The attributes that are replicated to the global catalog are identified in the schema as the partial attribute set (PAS) and are defined by default by Microsoft. However, to optimize searching, you can edit the schema by adding or removing attributes that are stored in the global catalog. In Windows 2000 Server environments, any change to the PAS results in full synchronization (update of all attributes) of the global catalog. Later versions of Windows Server reduce the impact of updating the global catalog by replicating only the attributes that change. In a single-domain forest, a global catalog server stores a full, writable replica of the domain and does not store any partial replica. A global catalog server in a single-domain forest functions in the same manner as a non-global-catalog server except for the processing of forest-wide searches.

NEW QUESTION: 4 What is the RAID level on an Avamar NDMP accelerator node? **A. 0 B. 1 C. 2 D. 3**
Answer: C
