NEW QUESTION: 2You have a server named Server 1. Server1 runs Windows Server 2012. Server1 has a thin provisioned disk named Disk1.You need to expand Disk1.Which two actions should you perform? (Each correct answer presents part of the solution. Choose two.)**A.** From File and Storage Services, extend Disk1.**B.** From File and Storage Services, detach Disk1.**C.** From File and Storage Services, add a physical disk to the storage pool.**D.** From Disk Management, extend the volume.**E.** From Disk Management, delete the volume, create a new volume, and then format the volume.**Answer: A,C****Explanation:**Step 1 (B): if required add physical disk capacity. Step 2 (A): Dynamically extend the virtual disk (not volume). Windows Server 2012 Storage Space subsystem now virtualizes storage by abstracting multiple physical disks into a logical construct with specified capacity. The process is to group selected physical disks into a container, the so-called storage pool, such that the total capacity collectively presented by those associated physical disks can appear and become manageable as a single and seemingly continuous space. Subsequently a storage administrator creates a virtual disk based on a storage pool, configure a storage layout which is essentially a RAID level, and expose the storage of the virtual disk as a drive letter or a mapped folder in Windows Explorer. C:Documents and Settingsusernwz1Desktop1.JPGThe system administrator uses File and Storage Services in Server Manager or the Disk Management tool to scan the disk, bring the disk online, and extend the disk size.C:Documents and Settingsusernwz1Desktop1.JPG <http://blogs.technet.com/b/yungchou/archive/2012/08/31/windows-server-2012-storagevirtualization-explained.aspx>

NEW QUESTION: 3Suspicious traffic without a specific signature was detected. Under further investigation, it was determined that these were false indicators. Which of the following security devices needs to be configured to disable future false alarms?**A.** Application based IPS**B.** Anomaly based ID**C.** Signature based IPS**D.** Signature based IDS**Answer: B****Explanation:** Most intrusion detection systems (IDS) are what is known as signature-based. This means that they operate in much the same way as a virus scanner, by searching for a known identity - or signature - for each specific intrusion event. And, while signature-based IDS is very efficient at sniffing out known s of attack, it does, like anti-virus software, depend on receiving regular signature updates, to keep in touch with variations in hacker technique. In other words, signature-based IDS is only as good as its database of stored signatures. Any organization wanting to implement a more thorough - and hence safer - solution, should consider what we

call anomaly-based IDS. By its nature, anomaly-based IDS is a rather more complex creature. In network traffic terms, it captures all the headers of the IP packets running towards the network. From this, it filters out all known and legal traffic, including web traffic to the organization's web server, mail traffic to and from its mail server, outgoing web traffic from company employees and DNS traffic to and from its DNS server. There are other equally obvious advantages to using anomaly-based IDS. For example, because it detects any traffic that is new or unusual, the anomaly method is particularly good at identifying sweeps and probes towards network hardware. It can, therefore, give early warnings of potential intrusions, because probes and scans are the predecessors of all attacks. And this applies equally to any new service installed on any item of hardware - for example, Telnet deployed on a network router for maintenance purposes and forgotten about when the maintenance was finished. This makes anomaly-based IDS perfect for detecting anything from port anomalies and web anomalies to mis-formed attacks, where the URL is deliberately mis-typed.
