NEW QUESTION: 4Your network consists of a singleActive Directory domain. All domain controllers run Windows Server 2008 R2.You need to implement a Certificate Services solution that meets the following requirements:-Automates the distribution of certificates for internal users -Ensures that the network's certificate infrastructure is as secure as possible -Gives external users access to resources that use certificate based authenticationWhat should you do?**A.** Deploy an online standalone root certification authority (CA). Deploy an offline standalone root **CB.** Deploy an online standalone root certification authority (CA). Deploy an online enterprise subordinate CA. Deploy an online standalone subordinate CA.**C.** Deploy an offline standalone root certification authority (CA). Deploy an online enterprise subordinate CA. Deploy an online standalone subordinate CA.**D.** Deploy an offline enterprise root certification authority (CA). Deploy an offline enterprise subordinate CA.**Answer: C**Explanation:Certification authority hierarchiesThe Microsoft public key infrastructure (PKI) supports a hierarchical

certification authority (CA) model. A certification hierarchy provides scalability, ease of administration, and consistency with a growing number of commercial and other CA products. In its simplest form, a certification hierarchy consists of a single CA. However, in general, a hierarchy will contain multiple CAs with clearly defined parent-child relationships. In this model, the child subordinate certification authorities are certified by their parent CA-issued certificates, which bind a certification authority's public key to its identity. The CA at the top of a hierarchy is referred to as the root authority, or root CA. The child CAs of the root CAs are called subordinate certification authorities (CAs). A root certification authority (CA) is the top of a public key infrastructure (PKI) and generates a self-signed certificate. This means that the root CA is validating itself (self-validating). This root CA could then have subordinate CAs that effectively trust it. The subordinate CAs receive a certificate signed by the root CA, so the subordinate CAs can issue certificates that are validated by the root CA. This establishes a CA hierarchy and trust path.

<http://social.technet.microsoft.com/wiki/contents/articles/2900.offline-root-certification-authority-ca.aspx> Certification authority hierarchies The Microsoft public key infrastructure (PKI) supports a hierarchical certification authority (CA) model. A certification hierarchy provides scalability, ease of administration, and consistency with a growing number of commercial and other CA products. In its simplest form, a certification hierarchy consists of a single CA. However, in general, a hierarchy will contain multiple CAs with clearly defined parent-child relationships. In this model, the child subordinate certification authorities are certified by their parent CA-issued certificates, which bind a certification authority's public key to its identity. The CA at the top of a hierarchy is referred to as the root authority, or root CA. The child CAs of the root CAs are called subordinate certification authorities (CAs). Authentication and Authorization Stand-alone CAs use local authentication for certificate requests, mainly through the Web enrollment interface. Stand-alone CAs provide an ideal service provider or commercial PKI provider platform for issuing certificates to users outside of an Active Directory environment where the user identity is separately verified and examined before the request is submitted to the CA. Offline and Online CAs Traditionally, the decision of whether to use either an online or offline CAs involves a compromise between availability and usability versus security. The more sensitive that the key material is and the higher the security requirements are, the less accessible the CA should be to users. Specifying CA Roles An ideal PKI hierarchy design divides the responsibility of the CAs. A topology that is designed with requirements that have been carefully considered provides the most flexible and scalable enterprise configuration. In general, CAs are organized in hierarchies. Single tier hierarchies might not provide adequate security compartmentalization, extensibility and flexibility. Hierarchies with more than three tiers might not provide additional value regarding security, extensibility and flexibility. The most important consideration is protecting the highest instance of trust as much as possible. Single-tier hierarchies are based on the need to compartmentalize risk and reduce the attack surface that is available to users who have malicious intent. A larger hierarchy is much more difficult to administer, with little security benefit. Depending on the organization's necessities, a PKI should consist of two or three logical levels that link several CAs in a hierarchy. Administrators who understand the design requirements for a three-level topology may also be able to build a two-level topology. A three-tier CA hierarchy consists of the following components: A root CA that is configured as a stand-alone CA without a network connection One or more intermediate CAs that are configured as stand-alone CAs without a network connection One or more issuing CAs that are configured as enterprise CAs that are connected to the network Also worth a look though it refers to windows 2003
