NEW QUESTION: 1

3層のeコマースウェブアプリケーションは現在オンプレミスでデプロイされており、スケーラビリティと弾力性を高めるためにAWSに移行されます。

Webサーバーは現在、ネットワーク分散ファイルシステムを使用して読み取り専用データを共有しています。アプリサーバー層は、IPマルチキャストに依存する検出と共有セッション状態のためにクラスタリングメカニズムを使用します。データベース層は、共有ストレージクラスタリングを使用してデータベースのフォールオーバー機能を提供し、スケーリングのために複数の読み取りスレーブを使用します。すべてのサーバーおよび分散ファイルシステムディレクトリ上のデータは、オフサイトテープに毎週バックアップされます。

どのAWSストレージおよびデータベースアーキテクチャがアプリケーションの要件を満たしていますか？ **A.**

Webサーバー：読み取り専用データをS3に保存し、ブート時にS3からルートボリュームにコピーします。アプリサーバー：

DynamoDBとIPマルチキャストの組み合わせを使用して状態を共有します。データベース：マルチAZ配置および1つ以上のリードレプリカでRDSを使用します。バックアップ：AMIを介して毎週バックアップされるWebサーバーとアプリサーバー、DBスナップショットを介してバックアップされるデータベース。 **B.** Webサーバー：EC2

NFSサーバーに読み取り専用データを保存します。起動時に各Webサーバーにマウントします。アプリサーバー：DynamoDBとIPマルチキャストの組み合わせを使用して状態を共有します。データベース：マルチAZ配置および1つ以上のリードレプリカでRDSを使用します。バックアップ：AMIを介して毎週バックアップされるWebサーバーとアプリサーバー、DBスナップショットを介してバックアップされるデータベース。 **C.**

Answer: A Explanation: Explanation Amazon RDS Multi-AZ deployments provide enhanced availability and durability for Database (DB) Instances, making them a natural fit for production database workloads. When you provision a Multi-AZ DB Instance, Amazon RDS automatically creates a primary DB Instance and synchronously replicates the data to a standby instance in a different Availability Zone (AZ). Each AZ runs on its own physically distinct, independent infrastructure, and is engineered to be highly reliable. In case of an infrastructure failure (for example, instance hardware failure, storage failure, or network disruption), Amazon RDS performs an automatic failover to the standby, so that you can resume database operations as soon as the failover is complete. Since the endpoint for your DB Instance remains the same after a failover, your application can resume database operation without the need for manual administrative intervention. Benefits Enhanced Durability Multi-AZ deployments for the MySQL, Oracle, and PostgreSQL engines utilize synchronous physical replication to keep data on the standby up-to-date with the primary. Multi-AZ deployments for the SQL Server engine use synchronous logical replication to achieve the same result, employing SQL Server-native Mirroring technology. Both approaches safeguard your data in the event of a DB Instance failure or loss of an Availability Zone. If a storage volume on your primary fails in a Multi-AZ deployment, Amazon RDS automatically initiates a failover to the up-to-date standby. Compare this to a Single-AZ deployment: in case of a Single-AZ database failure, a user-initiated point-in-time-restore operation will be required. This operation can take several hours to complete, and any data updates that occurred after the latest restorable time (typically within the last five minutes) will not be available. Amazon Aurora employs a highly durable, SSD-backed virtualized storage layer purpose-built for database workloads. Amazon Aurora automatically replicates your volume six ways, across three Availability Zones. Amazon Aurora storage is fault-tolerant, transparently handling the loss of up to two copies of data without affecting database write availability and up to three copies without affecting read availability. Amazon Aurora storage is also self-healing. Data blocks and disks are continuously scanned for errors and replaced automatically. Increased Availability You also benefit from enhanced database availability when running Multi-AZ deployments. If an Availability Zone failure or DB Instance failure occurs, your availability impact is limited to the time automatic failover takes to complete: typically under one minute for Amazon Aurora and one to two minutes for other database engines (see the RDS FAQ for details). The availability benefits of Multi-AZ deployments also extend to planned maintenance and backups. In the case of system upgrades like OS patching or DB Instance scaling, these operations are applied first on the standby, prior to the automatic failover. As a result, your availability impact is, again, only the time required for automatic failover to complete. Unlike Single-AZ deployments, I/O activity is not suspended on your primary during backup for Multi-AZ deployments for the MySQL, Oracle, and PostgreSQL engines, because the backup is taken from the standby. However, note that you may still experience elevated latencies for a few minutes during backups for Multi-AZ deployments. On instance failure in Amazon Aurora deployments, Amazon RDS uses RDS Multi-AZ technology to automate failover to one of up to 15 Amazon Aurora Replicas you have created in any of three Availability Zones. If no Amazon Aurora Replicas have been provisioned, in the case of a failure, Amazon RDS will attempt to create a new Amazon Aurora DB instance for you automatically. No Administrative Intervention DB Instance failover is fully automatic and requires no administrative intervention. Amazon RDS monitors the health of your primary and standbys, and initiates a failover automatically in response to a variety of failure conditions.

Failover conditions Amazon RDS detects and automatically recovers from the most common failure scenarios for Multi-AZ deployments so that you can resume database operations as quickly as possible without administrative intervention. Amazon RDS automatically performs a failover in the event of any of the following: Loss of availability in primary Availability Zone Loss of network connectivity to primary Compute unit failure on primary Storage failure on primary Note: When operations such as DB Instance scaling or system upgrades like OS patching are initiated for Multi-AZ deployments, for enhanced availability, they are applied first on the standby prior to an automatic failover. As a result, your availability impact is limited only to the time required for automatic failover to complete. Note that Amazon RDS Multi-AZ deployments do not failover automatically in response to database operations such as long running queries, deadlocks or database corruption errors.

NEW QUESTION: 2 In your production database, data manipulation language (DML) operations are executed on the SALES table. You have noticed some dubious values in the SALES table during the last few days. You are able to track users, actions taken, and the time of the action for this particular period but the changes in data are not tracked. You decide to keep track of both the old data and new data in the table long with the user information. What action would you take to achieve this task? **A.** Impose standard database auditing to audit SQL statements. **B.** Apply fine-grained auditing. **C.** Implement value-based auditing. **D.** Impose standard database auditing to audit object privileges. **Answer: B** Explanation:

NEW QUESTION: 3 Which is the Cisco recommended minimum viewing distance for a 52" monitor installed in a video conferencing room? **A.** 2.0 m **B.** 1.5 m **C.** 2.5 m **D.** 3.0 m **Answer: B**

NEW QUESTION: 4 Your network contains a single Active Directory domain. The domain contains a System Center Configuration Manager 2007 site and a System Center 2012 Configuration Manager site. You need to ensure that you can migrate objects from Configuration Manager 2007 to Configuration Manager 2012. What should you do? **A.** Extend the Active Directory schema and assign the Central Administration site server permissions to the System System Management container. **B.** Connect the Configuration Manager 2012 primary site as a child primary site of the Configuration Manager 2007 primary site. **C.** Connect the Configuration Manager 2007 primary site as a child primary site of the Configuration Manager 2012 primary site. **D.** Assign the computer account of the Central Administration site server permission to the Configuration Manager 2007 site. Assign the computer account of the Central Administration site server permission to the Microsoft SQL Server database instance. **Answer: D** Explanation: To migrate from a supported source hierarchy, you must have access to each applicable Configuration Manager source site, and permissions within the System Center 2012 Configuration Manager destination site to configure and run migration operations.
