**NEW QUESTION: 1** Organization A has been expanding and, as a result, is outgrowing the processing capacity of its on-premise Service A implementation. It is determined that this is due to usage thresholds of Service A and complex data processing limitations in Database A. The diagram depicts Organization A's current on-premise environment, where Service Consumers A, B and C attempt to access Service A at the same time. Service Consumer A successfully accesses Service A, which then successfully retrieves the requested data (1). Service Consumer B successfully accesses Service A, but due to the complex data structure, the request for the data times out and fails (2). Finally, Service Consumer C attempts to access Service A, but is rejected because Service A is unable to accept more concurrent requests. Organization A is required to continue using its on-premise Service A implementation, with the exception of Database A, which does not need to remain on-premise. Database A is dedicated to Service A and is comprised of relational data. Which of the following statements provides a solution that uses cloud-based IT resources to solve the performance limitations of Service A and Database A?  
**A.** A failover system can be implemented in a hybrid architecture comprised of Organization A's existing on-premise environment and a public cloud environment. The failover system would span both environments so that when Service A is unable to process request messages from Service Consumers A, B or C, the failover system can automatically route messages to a redundant implementation of Service A residing in the public cloud. Similarly, when Database A is unable to process a data access request from Service the failover system can automatically route this request to a redundant implementation of Database A, also residing in the public cloud.  
**B.** The state management database and resource replication mechanisms can be implemented to establish redundant implementations of Service A and Database A in both on-premise and cloud environments. Using resource replication, a cloud-based duplicate of Service A (Cloud Service A) will be established in a public cloud and will remain in synch with Service A via regular replication cycles. Using the resource replication mechanism together with the state management database mechanism allows for Database A to be dynamically replicated in an independent state management database that has redundant implementations in both on-premise and cloud environments. The state management database can be further optimized to support non-relational data to improve data access performance.  
**C.** A cloud bursting solution can be implemented, whereby a redundant copy of Service A is implemented within a public cloud. This cloud-based, redundant implementation of Service A is referred to as Cloud Service A. A copy of Database A is also implemented within the cloud and both the on-premise and cloud-based copies of Database A are redesigned to be non-relational in order to improve data access performance. Service A continues to act as a first point of contact for Service Consumers A, B and C and an automated scaling listener is deployed so that when Service A's thresholds are met, requests are automatically routed to Cloud Service A.  
**D.** None of the above  
**Answer: C**

**NEW QUESTION: 2** Which three are true regarding the use of Storage Indexes? **A.** Different storage regions may have different columns indexed for the same table. **B.** A maximum of eight table columns for any table are indexed per storage region. **C.** A Storage index is automatically maintained by CELLSRV based on the filter columns of the offload SQL. **D.** The use of Storage Indexes for particular categories of I/O can be disabled by using an I/O Resource Manager Category Plan. **E.** The use of Storage indexes for a particular database can be disabled by using an I/O Resource Manager Database Plan. **F.** Storage Indexes occupy space in the Smart Flash Cache. **Answer: A, B, C**  
**Explanation:** Explanation/Reference: Note: \* Storage indexes are used during smart scans. All the limitations to smart scans apply to storage indexes. They do not work with joins. Bind variables are supported, however it's slightly more restrictive than regular indexes/queries. \* The storage index is stored in the memory on each of the Exadata storage cells and is created and maintained transparently. However, if a storage cell is shutdown or rebooted the storage index will be lost from memory and will be recreated on subsequent accesses to the data after the cell has been brought back online. \* Storage Indexes are a very powerful capability provided in Exadata storage that helps avoid I/O operations. The Exadata Storage Server Software creates and maintains a Storage Index (that is, metadata about the database objects) in the Exadata cell. The Storage Index keeps track of minimum and maximum values of columns for tables stored on that cell. When a query specifies a WHERE clause, but before any I/O is done, the Exadata software examines the Storage Index to determine if rows with the specified column value exist in the cell by comparing the column value to the minimum and maximum values maintained in the Storage Index. If the column value is outside the minimum and maximum range, scan I/O for that query is avoided. Many SQL Operations run dramatically faster because large numbers of I/O operations are automatically replaced by a few lookups. To minimize operational overhead, Storage Indexes are created and maintained transparently and automatically by the Exadata Storage Server Software.

### NEW QUESTION: 3

あなたは、サードパーティのデータベースに対してフォーム認証を使用するASP.NET MVCアプリケーションを開発しています。あなたはユーザーを認証する必要があります。あなたは、どのコード部分を使わなければなりませんか? **A.** Option **DB.** Option **CC.** Option **BD.** Option **A**  
**Answer: A**  
**Explanation:** ASP.NET membership is designed to enable you to easily use a number of different membership providers for your ASP.NET applications. There are two primary reasons for creating a custom membership provider. \* You need to store membership information in a data source that is not supported by the membership providers included with the .NET Framework, such as a FoxPro database, an Oracle database, or other data sources. \* You need to manage membership information using a database schema that is different from the database schema used by the providers that ship with the .NET Framework. To implement a membership provider, you create a class that inherits the MembershipProvider abstract class from the System.Web.Security namespace. **Incorrect: Not C: Class ProviderBase** The provider model is intended to encapsulate all or part of the functionality of multiple ASP.NET features, such as membership, profiles, and protected configuration. **References:**

**NEW QUESTION: 4** 회사에 여러 AWS 계정이 있으며 결제 프로세스를 단순화하고 통합하려고 합니다. 어떤 AWS 서비스가 이를 달성할 수 있습니까? **A.** AWS 비용 및 사용 보고서 **B.** AWS 비용 탐색기 **C.** AWS 예산 **D.** AWS 조직 **Answer: D**  
**Explanation:** Explanation You can use the consolidated billing feature in AWS Organizations to consolidate billing and payment for multiple AWS accounts or multiple Amazon Internet Services Pvt. Ltd (AISPL) accounts. Every organization in AWS Organizations has a master (payer) account that pays the charges of all the member (linked) accounts. **Reference:**
